

ULTRASONIC SEEPAGE METER

FIELD OF THE INVENTION

[001] The present invention relates to an apparatus and method for measuring the velocity and other characteristics of submarine groundwater discharge as it enters or exits a surface water body, and more particularly to a remotely deployable time transient seepage meter that utilizes ultrasonic technology to continuously quantify and record the measured information. The present invention is intended for use in environmental fields including hydrology, oceanography, geology, ecology and all other related fields.

BACKGROUND OF THE INVENTION

[002] Understanding the exchange between seepage and overlying surface water has become increasingly important due to the potential impacts to the environment resulting from anthropogenic land uses. The key input for submarine groundwater discharge (SGD) in near-shore environments is believed to be the discharge from land to surface water induced by the hydraulic gradient in the terrestrial aquifer. However, significant contribution to SGD may also derive from groundwater circulation and oscillating flow induced by tidal stage as well as salinity and thermal variations. This discharge carries with it contaminants and/or nutrients, dissolved and/or colloidal, that have the potential to impact the chemical budget of surface water ecosystems. This impact, along with other biological and physical impacts, may be heightened in smaller bodies of water such as embayments or lagoons due to their limited volume and restricted fluid exchange with the open ocean.

[003] A major obstacle in studying SGD is accurately measuring groundwater seepage across the sediment-water interface. Discharge rates may be as low as < 1 cm/day and these low rates make quantification of SGD inherently difficult. In addition, the ebullition of gas from sediments is a common event, further increasing the difficulty of accurately measuring SGD.

[004] Current methodologies for measuring SGD have included a system that utilizes a 4-liter plastic collection bag and a cut off section of a 55 gallon drum as described by D.R. Lee, in "A Device for Measuring Seepage Flux in Lakes and Estuaries," *Limnology and Oceanography*, 22: 140-147, 1977. Using this device, the open-ended section of a cut off section of a 55-gallon drum is inserted into the sediment. Attached to the drum via an outflow port is a 4-liter plastic bag that collects the seepage.

The volume of the bag and sampling interval are recorded and the specific discharge velocity is obtained by dividing the volume of collected seepage over the time interval by the area of the drum. Although this method can be effective, various errors have been associated with the device that must be corrected for prior to sampling. Another disadvantage to this method is that it is quite labor intensive since the plastic bags need to be monitored and replaced continuously. In addition, data collected are averages over the specified time interval and may not fully quantify short term events. Furthermore, this method is incapable of measuring reverse flow.

[005] Continuous logging seepage meters have been developed utilizing heat-pulse technology as described by M. Taniguchi and Y. Fukuo, in "Continuous Measurements of Ground-Water Seepage Using an Automatic Seepage Meter," *Ground Water*, 31, no. 4: 675-679, 1993. This method, however, cannot be monitored during deployment and may therefore malfunction during the collection period without notice. Another disadvantage of this method is that it cannot measure seepage in intertidal environments in which the seepage meter becomes periodically air bound during low tide events. In addition, variations in the water density and temperature can also affect the accuracy of the heat pulse method.

[006] Piezometric head measurements have also been used to estimate the specific discharge of groundwater to surface waters. This method requires the installation of monitoring wells offshore to monitor the hydraulic head beneath the surface water. The method can determine if water is entering or exiting the surface water but in order to determine the specific discharge estimates of the hydraulic conductivity of the sediment are needed. However, this method is not a direct measurement of seepage but an estimate based on head measurements and sediment conductivity.

[007] Accordingly, there is a need for a remotely-deployable device capable of accurately measuring SGD in both the forward and reverse flow directions.

SUMMARY OF THE INVENTION

[008] It is the object of the present invention to overcome the shortcomings of previous methods to quantify SGD. The invention is intended to provide a robust, time transient meter that is able to continuously record the wide range of seepage rates observed in the field while providing a less labor intensive and more accurate method of quantifying SGD in both the forward and reverse flow directions.

[009] One advantage of the present invention is to be able to continuously record groundwater discharge in subsurface (intertidal and subsurface) environments. Another feature of the present invention is the ability to utilize velocity of sound data collected by the meter to determine the salinity and therefore source of the water passing through the seepage meter. This feature provides an advantage over other methods by differentiating terrestrial groundwater from surrounding surface water in marine environments.

Therefore, the source of the discharge and any toxic or hazardous constituents present in the discharge is more easily determined and quantified. Another advantage of the present invention is the ability to accurately and continuously quantify very low flow rates regardless of changes in the temperature, density or the affect of ebullition of gases from the sediments.

[010] The above and other objects, advantages, and features are accomplished by providing a mechanism capable of quantifying groundwater seepage rate and quality. A seepage meter in accordance with the present invention generally comprises a funneling device to collect the groundwater flow through an inlet which then discharges through this device via a discharge outlet, for recording water temperature, tidal stage, and electrical conductance using probes mounted in the device; an ultrasonic flow tube, for accepting the discharge from the collection device through a collection inlet and discharging the groundwater through a discharge outlet; a data logger, connected to the flow tube which sends signal to the flow tube and receives data from the flow tube which then is used to determine the flow rate of groundwater through the flow tube.

[011] Further, in accordance with the above objects, advantages, and features the present invention provides a device that quantifies the rate of submarine groundwater discharge using inlet means, outlet means, connected to the inlet and outlet means for determining seepage rate; control means, for sending signal to the flow tube; recording means, to quantify seepage rate using travel time data from the flow tube; valve means, for transferring discharge from the collection device to an additional discharge outlet connected to a pump for sampling.

[012] In further accordance with the above objects, advantages, and features the present invention provides a methodology for quantifying submarine groundwater discharge by utilizing a) collecting water through a collection funnel, b) directing the

collected water through an in line ultrasonic flow tube, c) using a data logger to quantify and record flow rate, and d) repeating steps a) through c).

BRIEF DESCRIPTION OF THE SEVERAL DRAWINGS

[013] **FIG. 1** is a perspective view of a preferred embodiment of an ultrasonic seepage meter in accordance with the present invention.

[014] **FIG. 2** is a partial view of the ultrasonic seepage meter of **FIG. 1**.

[015] **FIG. 3** is a partial cutaway view of the flow meter of the ultrasonic seepage meter of **FIG. 1**.

[016] **FIG. 4** is a partial side cutaway view of the ultrasonic seepage meter of **FIG. 1**.

[017] **FIG. 5** is a graph illustrating data recorded using the ultrasonic seepage meter of **FIG. 1** in West Neck Bay.

DETAILED DESCRIPTION OF THE INVENTION

[018] **FIGS. 1 and 2** illustrate a preferred embodiment of an ultrasonic seepage meter **100** in accordance with the present invention. Generally, ultrasonic seepage meter **100** comprises collection funnel **110**, flow meter **140**, and controller logger **160**. Collection funnel **110**, as shown in **FIGS. 1 and 2**, further comprises an open bottom **112** and an enclosed top **114**. The sides of collection funnel **110** form a square, each side being 0.46 m in length (corresponding to a capture area $A = 0.21 \text{ m}^2$), and at least 10 cm tall. However, it can be appreciated that collection funnel **110** may be of many different types of geometries and still be within the spirit of the present invention. Extending from side **116** of funnel **110** is discharge outlet **120**. Discharge outlet **120** may also further comprise valve **122**, which may be a ball valve. In a preferred embodiment, the top **114** of funnel **110** is angled so that the side **116** with discharge outlet **120** is slightly higher than the other side of funnel **110** (see **FIG. 4**).

[019] Flow meter **140** is fluidly connected to discharge outlet **120**. In a preferred embodiment, tygon tubing **124** is used to fluidly connect discharge outlet **120** with flow meter **140**.

[020] As shown in **FIG. 3**, flow meter **140** comprises inlet **144**, outlet **146**, ultrasonic flow tube **150**, and piezoelectric transducers **152**. In a preferred embodiment, ultrasonic flow tube **150** is a Controlotron ultrasonic flow tube (U.S. Patent No. 5,467,321). Inlet **144**, outlet **146**, and ultrasonic flow tube **150** are fluidly connected to

each other by tygon tubing 154. As water discharges from the collection funnel 110 it enters the flow meter 140 at inlet 144 and passes through tygon tubing 152 into ultrasonic flow tube 150. Two piezoelectric transducers 152 mounted at opposite ends of ultrasonic flow tube 150. Outlet 146 may further comprise a valve 142, which may be a ball valve. The components of the flow meter 140 are enclosed within watertight casing 159.

[021] Piezoelectric transducers 152 continually generate bursts of ultrasonic signals from one end of ultrasonic flow tube 150 to the other end. Typically ~250 bursts are transmitted per second, and each burst is made up of ~40 periodic ultrasonic waves. As water flows through ultrasonic flow tube 150, the speed by which the water is moving through the flow tube affects the speed of the ultrasonic signals. Arrival of the ultrasonic signals is continuously monitored by piezoelectric transducers 152 which are in communication with control logger 160. Measurement of the sound waves provides the velocity data needed. The discharge exits through outlet 146.

[022] Controller logger 160 is attached to the outside of the funnel 110 and is encased in water tight housing 161. Control logger 160 comprises a control module and a data logger and is in operative communication with flow meter 140. Control logger 160 controls the operation of flow meter 140 and also collects data received from flow meter 140. In a preferred embodiment (not shown), housing 161 has a clear end cap which displays controls that can be changed by the use of a magnetic wand. This allows for controller logger 160 to be programmed while underwater. In another embodiment, an rs232 port in housing 161 may be provided as an alternative programming source. Power supply 170 provides power to control logger 160 and flow meter 140. Power supply 170 is also encased in water tight housing 171.

[023] As shown in FIG. 2, collection funnel 110 may also be provided with a probe 190 to measure other environmental data. In a preferred embodiment, a Solinst 3001 LTC probe (U.S. Patent No. 5,117,698) that continuously records tidal stage, electrical conductance, and temperature of the water within the collection funnel. In a preferred embodiment, probe 190 is a self contained module with its own control and data collection system. In addition, collection funnel 110 may be equipped with port 302 through which water within collection funnel 110 may be sampled, as further described below.

[024] In a typical application, as illustrated in **FIG. 4**, ultrasonic seepage meter **100** is installed into the bottom sediment of a marine or surface water environment. Collection funnel **110** is inserted into the bottom sediment in a marine or surface water environment, preferably to a depth of 10 cm. Funnel **110** preferably is installed so that bottom **112** is substantially parallel to the top surface of the bottom sediment, resulting in top **114** being angled slightly. This configuration and placement of funnel **110** creates a reliable seal with the sediment and reduces the chance of short-circuiting due to bottom heterogeneity or bio-irrigation from marine organisms, *i.e.*, allows funnel **110** to effectively capture SGD. Because top **114** is angled slightly, discharge outlet **120** is slightly more elevated from the sediment bottom than the rest of funnel **110**. This allows air and/or other gases ebulliating from the sediment to escape from funnel **110** through discharge outlet **120**. By pressing funnel **110** into the sediment so that the lowest edge of top **114** is level with the sediment, headspace **118** (the open volume of funnel **110** above the sediment) is minimized, allowing for efficient flow of seepage fluid through funnel **110** and discharge outlet **120**.

[025] A field calibration is performed on the system by conducting a zero test. Valves **122** and **142** on the collection funnel **110** and the flow meter outlet **142** are both turned to the closed position. Control logger **160** is then programmed to perform a zero calibration so that travel times for the ultrasound waves are calibrated at a zero flow rate. Upon completion, valves **122** and **142** are reopened and the logger is programmed for data collection. In a preferred embodiment, the control logger is programmed to collect data at intervals from once every second to once every 24 hours. Control logger **160**, may also be programmed to collect data such as time, date, site identification, flow rate, mean flow rate, total flow rate, velocity of sound, change in arrival times, and percent aeration in the flow tube **150**. This data may be provided by sensors **180** located within flow tube **150** (see **FIG. 3**) and operatively connected to control logger **160**. Methods of doing this are well known in the art. In a preferred embodiment, flow rates are measured in units of volume per time (cm^3/s) and a seepage velocity is obtained by dividing the calculated flow rate by the area of collection funnel **110**.

[026] The correlation between the salinity of water and the velocity of sound waves in the saline water under static flow conditions at a fixed temperature is well known. Therefore, the salinity of the groundwater discharge can be inferred from the

average of the upstream and downstream speeds of the ultrasound waves through the flow tube, if the groundwater temperature is simultaneously measured. This information will assist the user in differentiating terrestrial groundwater from surrounding surface water in marine environments. Thus, the source of the discharge and any toxic or hazardous constituents present in the discharge may be more easily determined and quantified.

[027] Laboratory and field calibrations show that the ultrasonic flow meter **100** can resolve groundwater discharges on the order of $0.1 \mu\text{m/s}$ ($<1\text{cm/d}$), and it is sufficiently robust for deployment in the field for several days. The ability to acquire data at high rate (up to 400 times per second) allows the system to tolerate temperature density and aeration affects and still produces high-resolution accurate measurements. Flow meter **100** has also been found to be effective in measuring reverse flow rate, such as when a negative groundwater flux in which the overlying surface water is recharging the seepage zone.

[028] The present invention has been field tested and data show a relationship between seepage rate, tidal stage and hydraulic gradient from the onshore aquifer connection. This relationship results from the cyclic head changes that overlie the seepage zone and associated changes in hydraulic gradient. As tide rises, the receiving surface water hydraulic head is increasing, therefore limiting the vertical gradient between the seepage and the surface water. This leads to a decrease in the seepage flux across the sediment-water interface. As the tide is lowered, the vertical gradient begins to increase. An example data set collected in West Neck Bay, Shelter Island, NY is shown in **FIG. 5**, where it can be seen that the maximum (and minimum) in tidal elevation do not correspond exactly to the minimum (and maximum) of seepage rate. In this data set, the phase lag between the tidal elevation and the seepage rate was $\sim 1\frac{1}{2}$ hours. This was presumably due to the transient fluctuation of the water table in response to tidal loading.

[029] The present invention has the ability to be used to quantify contaminant or nutrient loading into a surface water body resulting from submarine groundwater discharge. Preferably, sampling occurs shortly after low tide corresponding to the maximum groundwater seepage rate (see **FIG. 5**). Prior to sampling, the rate of seepage is observed. The valves **122** and **142** of both the flow meter **140** and the collection funnel **110** are closed and tygon tubing (not shown) is connected to the collection funnel **110** at

port **195**. The tubing is connected to a manual peristaltic pump and water is pumped from the collection funnel **110** at a rate equal to the rate observed from the data logger prior to the closing of valves **122** and **142**. This way, measurements are taken as close as possible to actual conditions. This water is collected and taken to the laboratory for analysis. Upon completion of the sampling, the valves **122** and **142** are reopened and collection of seepage rate data may be resumed.

[030] It can be readily seen by those skilled in the art that a seepage meter in accordance with the present invention may take many different configurations in addition to the ones presented here while remaining within the spirit and scope of the present invention. Accordingly, it should be clearly understood that the embodiments of the invention described above are not intended as limitations on the scope of the invention, which is defined only by the following claims.
